Dyou can view an RNN as a fancy way of representing a fer-loop. For instance, we previously represented a loop that determines whether there are at least 3 Gs in a DNA sequence.

for 
$$x$$
 in  $X$ :

if  $x == "G"$  and not  $Q[1]$ :

 $Q[1] = True$ 

elif  $x == "G"$  and not  $Q[2]$ :

 $Q[2] = True$ 

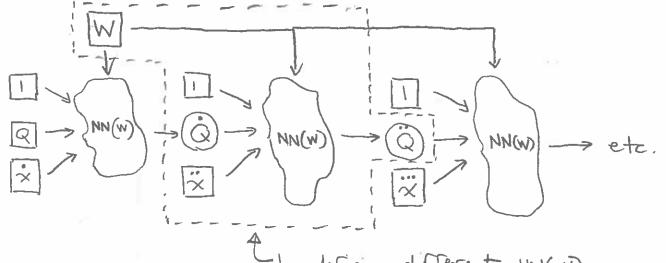

elif  $x == "G"$  and not  $Q[3]$ :

 $Q[3] = True$ 

2) We used the following neural net:

where: 
$$\mathcal{R} = \mathcal{W}^T \begin{bmatrix} 1 \\ \mathcal{C} \\ \mathcal{X} \end{bmatrix}$$
 and  $\mathcal{Q} = \mathcal{Q}(\mathcal{R})$ 

3) For each iteration, we use a single fully connected layer, followed by an activation function. But there's nothing stopping us from using a more complicated neural network to compute the next state at each iteration:

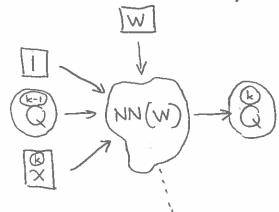

by defining different NN(W), we can make different, more powerful RNNs.

4) Notice that we can structure NN(W) to enable more complex logic in each iteration of the loop:

for x in X:

| complex logic
| goes here

complex logic goes here

5) Let's try encoding a somewhat more complicated function. Suppose we want to determine whether a bitstring contains at least four sequences of three consecutive ones, e.g.

$$0 \frac{1}{1} \frac{1}{2} \frac{1}{3} \frac{1}{4} \frac{1}{4}$$

Note that overlapping sequences still count.

One way to write this as a function:

def f(X: bitstring):

| count = 0
| streak = 0

tmpcount=0 tmpstreak=0 for ch in X+"0":

> if ch == 0: streak = 0

> > Streak += 1

if typstreak >= 3.

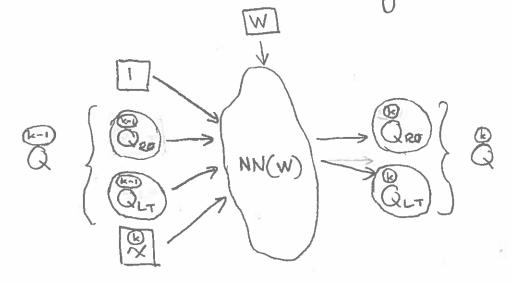

tmpcount = count tmpstreak = streak

return count >= 4

For our state variables Q, we'll use our variables count and streak.

But we'll actually make two copies of each: a "long-term" version and a "read-only" version:

So we'll be trying to find a good neural network architecture of the following form

LONG SHORT-TERM	MEMORY NETWORK	S
	O	

3) Let's trace out the desired functionality of NN(W) in terms of the long-term state variables. Suppose our bitstring is 0111011110 and we're starting the fifth iteration, i.e.

9) We'd like to go through the following steps:

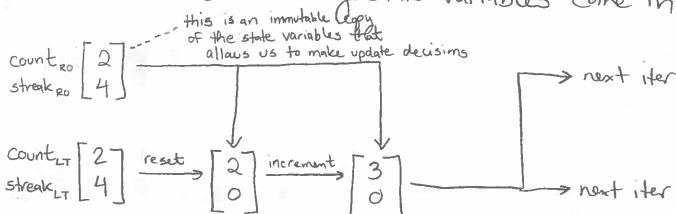

10 Similarly, for the next iteration:

LONG SHORT-TERM MEMORY NETWORKS
1) Going through the next Few iterations:
011101110
count [ ] reset [ ] increment [ ]
011101110 to 2 because we encountered another one
steak [2] reset [1] increment [1]  steak [2]
0111011110 count gets incremented
count [1] reset [1] increment [2] streak was > 3 at the streak [3] [4] the iteration's start
0111011110
Count [2] reset [2] increment [3]  Streak [4] [0]
because we encountered
9 zero in the bitstring
$\mathcal{O}$

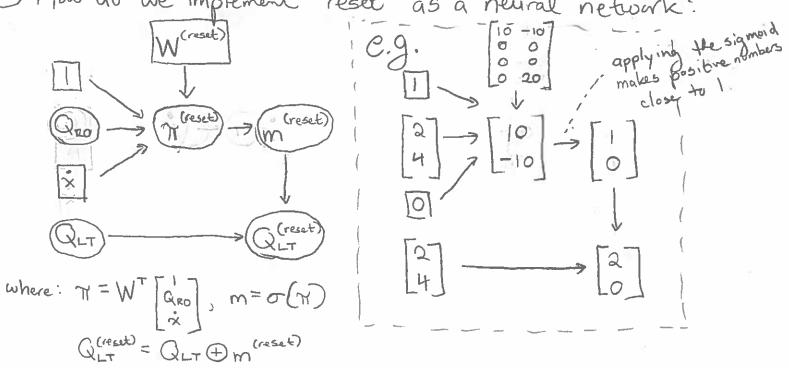

(12) Notice particularly the last Heration:

But we wiped out the streak during the reset, so how do we implement the increment of count?

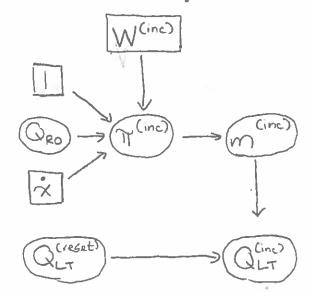

(3) This is where the read-only state variables come in:

(4) How do we implement "reset" as a neural network!

15) How do we implement "increment" as a neural network?

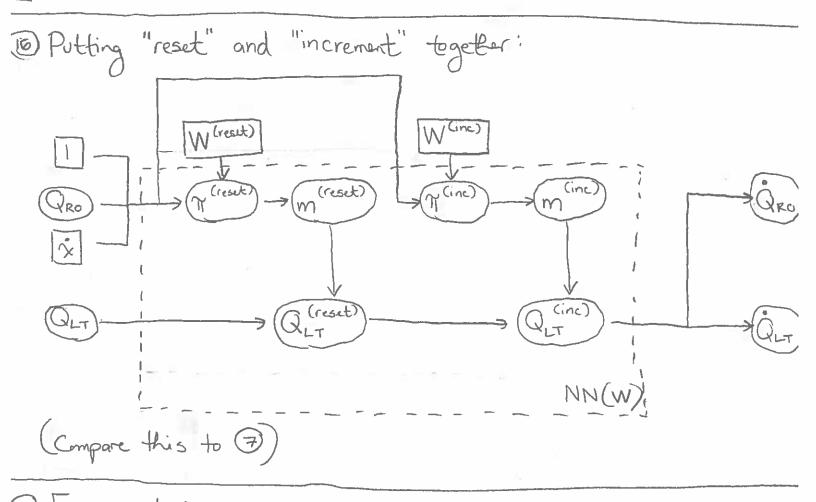

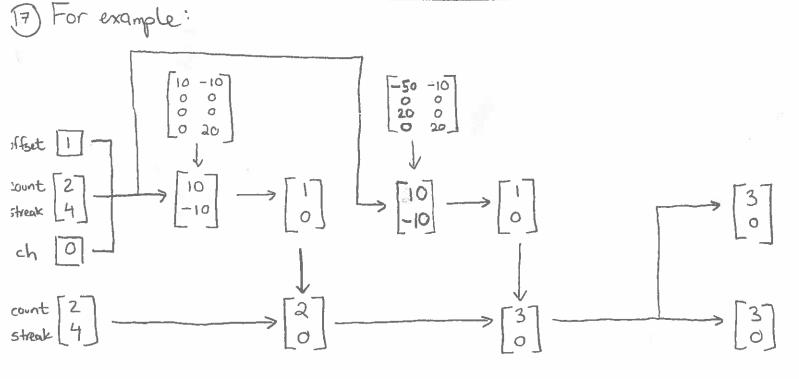

$$\begin{bmatrix} 2 \\ 4 \end{bmatrix} = \begin{bmatrix} 20 & -10 \\ 0 & 0 \\ 0 & 20 \end{bmatrix}$$

$$\begin{bmatrix} 20 \\ -10 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 \\ 4 \end{bmatrix} = \begin{bmatrix} 3 \\ 0 \end{bmatrix}$$

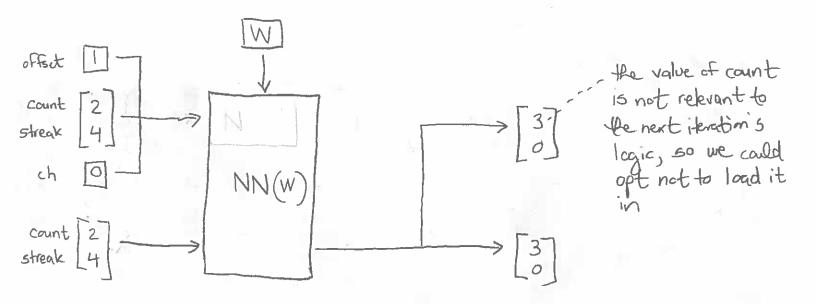

where: 
$$M = W^T \begin{bmatrix} 1 \\ Q_{RO} \\ \dot{\chi} \end{bmatrix}$$

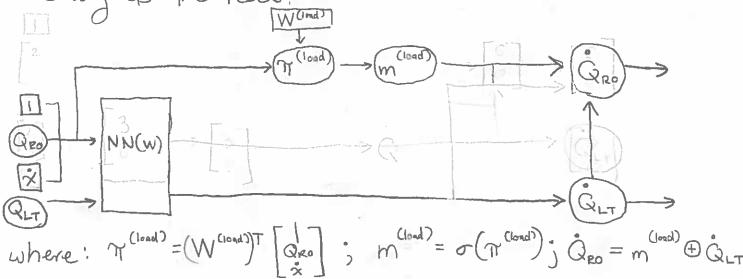

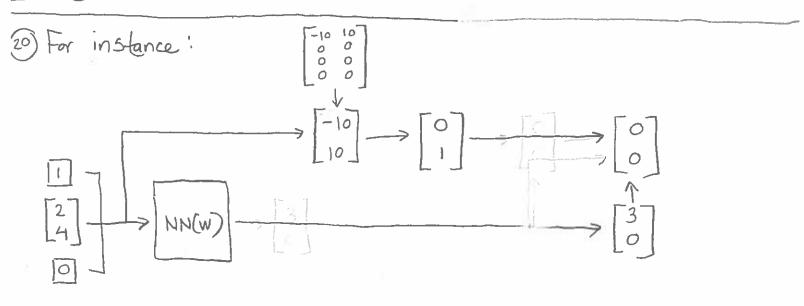

(18) The RNN depicted in (16) is close to something called a Long Short-Term Memory network (LSTM). Full LSTMs have a caple additional extensions.

First, the LSTM does not have to load everything from the long-term memory back into the read-only buffer for the next iteration.

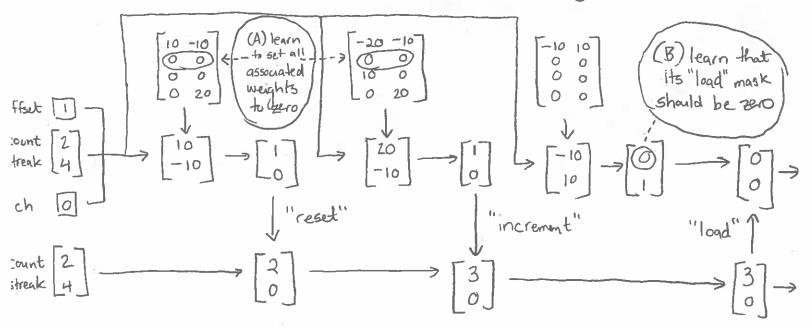

(9) Zeroing at irrelevant state variables can be achieved the same way as the reset.

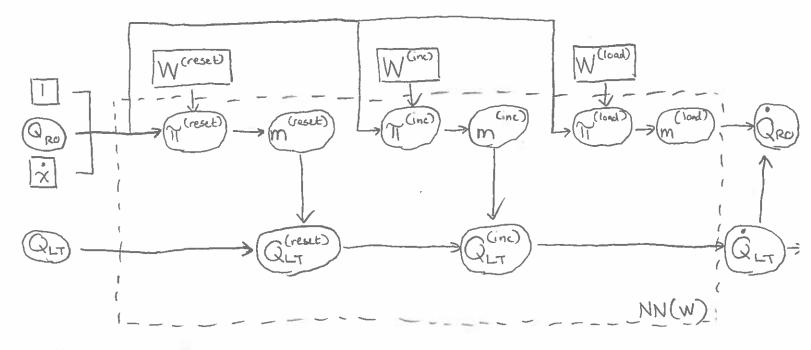

21) Why load selectively? It certainly doesn't harm flings (from a representational perspective) to load the entire long-term memory into the read-only buffer every iteration.

However, it may make it easier to learn the function. Consider to count variable, which is never needed in the read-only buffer. In order to ignore it, you can either

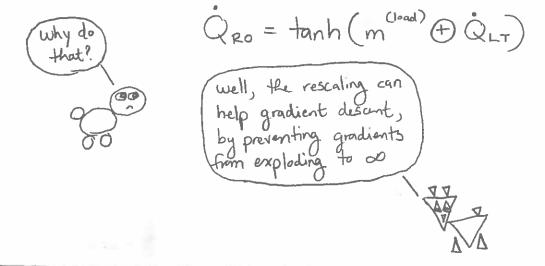

Option B often requires less parameters to learn.

2 Adding the "load" to our RNN gives US:

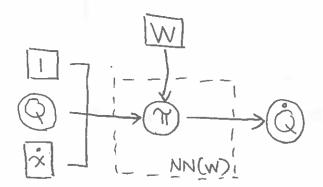

where:

23) The final extension needed to turn this into a standard LSTM is the addition of a couple tanh activations in strategic places, e.g. to rescale the values in the read-only buffer to be between -1 and 1, i.e.

24) Anyways, even comparing our LSTM-life with the vanilla RNN:

it's clear that it's much more complicated. However it does tend to work better, particularly for long sequential iterations. This is generally attributed to the long-term state, which allows the network to "remember" information that may only be relevant much later in the sequence.

- 25) As an example of when these "long term relevancies" might occur, consider the task of corecerence resolution in English.
  - "Suppose two integers sum to seven, and moreover, the product of the numbers is tuelve. If so, what are the two numbers?"

If an RNN is processing this passage word by word, then it needs the capacity to store information about the "two integers" and retrieve it much later in the passage (both when it is stated that the product of the numbers is twelve, and when it is asked what the two numbers are).
